Package 'permutations'

July 17, 2024

Type Package

Title The Symmetric Group: Permutations of a Finite Set

Version 1.1-5

Imports magic,numbers,partitions (>= 1.9-17),freealg (>= 1.0-4)

Maintainer Robin K. S. Hankin <hankin.robin@gmail.com>

Depends R (>= 3.5.0), methods

LazyData TRUE

Description Manipulates invertible functions from a finite set to itself. Can transform from word form to cycle form and back. To cite the package in publications please use Hankin (2020) ``Introducing the permutations R package'', SoftwareX, volume 11 <doi:10.1016/j.softx.2020.100453>.

License GPL-2

allperms   *All permutations with given characteristics*

Description

Functionality to enumerate permutations given different characteristics. In the following, n is assumed to be a non-negative integer. Permutations, in general, are coerced to cycle form.

- allperms(n) returns all $n!$ permutations of $[n]$.
- allcycn() returns all $(n-1)!$ permutations of $[n]$ comprising a single cycle of length n.
- allcyc(s) returns all single-cycle permutations of set s. If s has a repeated value, an opaque error message is returned.
- allpermslike(o) takes a length-one vector o of permutations and returns a vector comprising permutations with the same shape and cycle sets as it argument.
- some_perms_shape(part) takes an integer partition part, as in a set of non-negative integers, and returns a vector comprising every permutation of size sum(part) with shape part that has its cycles in increasing order.
- all_cyclic_shuffles(u) takes a permutation u and returns a vector comprising of all permutations with the same shape and cycle sets. It is vectorised so that argument u may be a vector of permutations.
- all_perms_shape(p) takes a permutation p and returns a vector of all permutations of size sum(p) and shape p.

Usage

```
allperms(n)
allcycn(n)
allcyc(s)
allpermslike(o)
some_perms_shape(shape)
all_cyclic_shuffles(o)
all_perms_shape(shape)
```

Arguments

shape	A set of strictly positive integers, interpreted as the shape of a partition
s	A set of strictly positive integers, interpreted as a set on which permutations are defined
n	The size of the permutation
o	A vector of permutations, coerced to cycle form. Function `allpermslike()` considers only the first element

Details

Function `allperms()` is very basic (the idiom is `word(t(partitions::perms(n))))`) but is here for completeness.

Note

Function `allcyc()` is taken directly from Er's "fine-tuned" algorithm. It should really be implemented in C as part of the **partitions** package but I have not yet got round to this.

Author(s)

Robin K. S. Hankin

all_perms_shape(c(2,2,3))
```

---

as.function.permutation

Coerce a permutation to a function

Description

Coerce a permutation to an executable function

Usage

```
## S3 method for class 'permutation'
as.function(x, ...)
```

Arguments

x	permutation
...	further arguments (currently ignored)

Note

Multiplication of permutations loses associativity when using functional notation; see examples.

Also, note that the coerced function will not take an argument greater than the size (qv) of the permutation.

Author(s)

Robin K. S. Hankin

Examples

```
x <- cyc_len(3)
y <- cyc_len(5)

xfun <- as.function(x)
yfun <- as.function(y)

stopifnot(xfun(yfun(2)) == as.function(y*x)(2)) # note transposition of x & y

# written in postfix notation one has the very appealing form x(fg) = (xf)g

# it's vectorized:
as.function(rperm(10,9))(1)
as.function(as.cycle(1:9))(sample(9))
```

---

c *Concatenation of permutations*

Description

Concatenate words or cycles together

Usage

```
## S3 method for class 'word'
c(...)
## S3 method for class 'cycle'
c(...)
## S3 method for class 'permutation'
rep(x, ...)
```

Arguments

...	In the methods for c(), objects to be concatenated. Must all be of the same type: either all word, or all cycle
x	In the method for rep(), a permutation object

Note

The methods for c() do not attempt to detect which type (word or cycle) you want as conversion is expensive.

Function rep.permutation() behaves like base::rep() and takes the same arguments, eg times and each.

size

Examples

```
x <- as.cycle(1:5)
y <- cycle(list(list(1:4,8:9),list(1:2)))

# concatenate cycles:
c(x,y)

# concatenate words:
c(rperm(5,3),rperm(6,9))   # size adjusted to maximum size of args
```

```
# repeat words:
rep(x, times=3)
```

---

capply   *Apply functions to elements of a cycle*

Description

Function `capply()` means "cycle apply" and is modelled on `lapply()`. It applies a function to every element in the cycles of its argument.

Usage

```
capply(X, fun, ...)
```

Arguments

X	Permutation, coerced to cycle
fun	Function to be applied to each element of X
...	Further arguments to fun()

Details

This function is just a convenience wrapper really.

Value

Returns a permutation in cycle form

Note

Function `allcyc()` is a nice application of `capply()`.

Author(s)

Robin K. S. Hankin

See Also

[allcyc](#)

Examples

```
(x <- rperm())
capply(x,function(x){x+100})
capply(x,rev)

all(is.id(capply(x,rev)*x))  # should be TRUE

capply(rcyc(20,5,9),sort)

capply(rcyc(20,5,9),sample)  # still 5-cycles

capply(cyc_len(1:9),\(x)x[x>4])

capply(cyc_len(1:9),\(x)x^2)
```

---

cayley	*Cayley tables for permutation groups*

Description

Produces a nice Cayley table for a subgroup of the symmetric group on n elements

Usage

```
cayley(x)
```

Arguments

x   A vector of permutations in cycle form

Details

Cayley's theorem states that every group G is isomorphic to a subgroup of the symmetric group acting on G. In this context it means that if we have a vector of permutations that comprise a group, then we can nicely represent its structure using a table.

If the set x is not closed under multiplication and inversion (that is, if x is not a group) then the function may misbehave. No argument checking is performed, and in particular there is no check that the elements of x are unique, or even that they include an identity.

Value

A square matrix giving the group operation

Author(s)

Robin K. S. Hankin

Examples

```
## cyclic group of order 4:
cayley(as.cycle(1:4)^(0:3))

## Klein group:
K4 <- as.cycle(c("()","(12)(34)","(13)(24)","(14)(23)"))
names(K4) <- c("00","01","10","11")
cayley(K4)

## S3, the symmetric group on 3 elements:
S3 <- as.cycle(c(
    "()",
    "(12)(35)(46)", "(13)(26)(45)",
    "(14)(25)(36)", "(156)(243)", "(165)(234)"
))
names(S3) <- c("()","(ab)","(ac)","(bc)","(abc)","(acb)")
cayley(S3)

## Now an example from the onion package, the quaternion group:
## Not run:
 library(onion)
 a <- c(H1,-H1,Hi,-Hi,Hj,-Hj,Hk,-Hk)
 X <- word(sapply(1:8,function(k){sapply(1:8,function(l){which((a*a[k])[l]==a)})}))
 cayley(X)  # a bit verbose; rename the vector:
 names(X) <- letters[1:8]
 cayley(X)  # more compact

## End(Not run)
```

| commutator | *Group-theoretic commutator: the dot object* |

Description

In the **permutations** package, the dot is defined as the **Group-theoretic commutator**: $[x, y] = x^{-1}y^{-1}xy$. This is a bit of an exception to the usual definition of xy-yx (along with the **freegroup** package). Package idiom is commutator(x,y) or .[x,y].

The Jacobi identity does not make sense in the context of the **permutations** package, but the Hall-Witt identity is obeyed.

The "dot" object is defined and discussed in inst/dot.Rmd, which creates file data/dot.rda.

Usage

```
commutator(x, y)
```

Arguments

x, y   Permutation objects, coerced to word

Author(s)

Robin K. S. Hankin

Examples

```
.[as.cycle("123456789"),as.cycle("12")]

x <- rperm(10,7)
y <- rperm(10,8)
z <- rperm(10,9)

uu <-
commutator(commutator(x,y),z^x) *
commutator(commutator(z,x),y^z) *
commutator(commutator(y,z),x^y)

stopifnot(all(is.id(uu)))  # this is the  Hall-Witt identity

.[x,y]

is.id(.[.[x,y],z^x] * .[.[z,x],y^z] * .[.[y,z],x^y])
is.id(.[.[x,-y],z]^y * .[.[y,-z],x]^z * .[.[z,-x],y]^x)
```

---

  conjugate   *Are two permutations conjugate?*

Description

Returns TRUE if two permutations are conjugate and FALSE otherwise.

Usage

```
are_conjugate(x, y)
are_conjugate_single(a,b)
```

Arguments

x, y, a, b   Objects of class permutation, coerced to cycle form

Details

Two permutations are conjugate if and only if they have the same shape. Function are_conjugate()
is vectorized and user-friendly; function are_conjugate_single() is lower-level and operates
only on length-one permutations.

The reason that are_conjugate_single() is a separate function and not bundled inside are_conjugate()
is that dealing with the identity permutation is a pain in the arse.

Value

Returns a vector of Booleans

Note

The functionality detects conjugateness by comparing the shapes of two permutations; permutations
are coerced to cycle form because function shape() does.

The group action of conjugation, that is x^y or y^-1 x y, is documented at conjugation.

```
are_conjugate(x,conjugate(x^y))
```

is always TRUE.

Author(s)

Robin K. S. Hankin

stopifnot(all(are_conjugate(megaminx,megaminx^as.cycle(sample(129)))))
```

---

cyclist   *details of cyclists*

Description

Various functionality to deal with cyclists

Usage

```
vec2cyclist_single(p)
vec2cyclist_single_cpp(p)
remove_length_one(x)
cyclist2word_single(cyc,n)
nicify_cyclist(x,rm1=TRUE, smallest_first=TRUE)
```

Arguments

p	Integer vector, interpreted as a word
x, cyc	A cyclist
n	In function `cycle2word_single()`, the size of the permutation to induce
rm1, smallest_first	
	In function `nicify_cyclist()`, Boolean, governing whether or not to remove length-1 cycles, and whether or not to place the smallest element in each cycle first (non-default values are used by `standard_cyclist()`)

Details

A *cyclist* is an object corresponding to a permutation P. It is a list with elements that are integer vectors corresponding to the cycles of P. This object is informally known as a cyclist, but there is no S3 class corresponding to it. In general use, one should not usually deal with cyclists at all: they are internal low-level objects not intended for the user.

An object of S3 class *cycle* is a (possibly named) list of cyclists. NB: there is an unavoidable notational clash here. When considering a single permutation, "cycle" means group-theoretic cycle [eg $1 \longrightarrow 2 \longrightarrow 3 \longrightarrow 1$]; when considering R objects, "cycle" means "an R object of class *cycle* whose elements are permutations written in cycle form".

The elements of a cyclist are the disjoint group-theoretic cycles. Note the redundancies inherent: firstly, because the cycles commute, their order is immaterial (and a list is ordered); and secondly, the cycles themselves are invariant under cyclic permutation. Heigh ho.

A cyclist may be poorly formed in a number of ways: the cycles may include repeats, or contain elements which are common to more than one cycle. Such problems are detected by `cyclist_valid()`. Also, there are less serious problems: the cycles may include length-one cycles; the cycles may start with an element that is not the smallest. These issues are dealt with by `nicify_cyclist()`.

- Function `nicify_cyclist()` takes a cyclist and puts it in a nice form but does not alter the permutation. It takes a cyclist and removes length-one cycles; then orders each cycle so that

the smallest element appears first (that is, it changes (523) to (235)). It then orders the cycles by the smallest element. Function `nicify_cyclist()` is called automatically by `cycle()`. Remember that `nicify_cyclist()` takes a cyclist!

- Function `remove_length_one()` takes a cyclist and removes length-one cycles from it.
- Function `vec2cyclist_single()` takes a vector of integers, interpreted as a word, and converts it into a cyclist. Length-one cycles are discarded.
- Function `vec2cyclist_single_cpp()` is a placeholder for a function that is not yet written.
- Function `cyclist2word_single()` takes a cyclist and returns a vector corresponding to a single word. This function is not intended for everyday use; function `cycle2word()` is much more user-friendly.
- Function `char2cyclist_single()` takes a character string like "(342)(19)" and turns it into a cyclist, in this case `list(c(3,4,2),c(1,9))`. This function returns a cyclist which is not necessarily canonicalized: it might have length-one cycles, and the cycles themselves might start with the wrong number or be incorrectly ordered. It attempts to deal with absence of commas in a sensible way, so "(18,19)(2,5)" is dealt with appropriately too. The function is insensitive to spaces. Also, one can give it an argument which does not correspond to a cycle object, eg `char2cyclist_single("(94)(32)(19)(1)")` (in which "9" is repeated). The function does not return an error, but to catch this kind of problem use `char2cycle()` which calls the validity checks.

  The user should use `char2cycle()` which executes validity checks and coerces to a cycle object.

See also the "cyclist" vignette [type `vignette("cyclist")` at the command line] which contains more details and examples.

[as.cycle](),[fbin](),[valid]()

Examples

```
vec2cyclist_single(c(7,9,3,5,8,6,1,4,2))

char2cyclist_single("(342)(19)")

nicify_cyclist(list(c(4, 6), c(7), c(2, 5, 1), c(8, 3)))
nicify_cyclist(list(c(4, 6), c(7), c(2, 5, 1), c(8, 3)),rm1=TRUE)

nicify_cyclist(list(c(4, 6), c(7), c(2, 5, 1), c(8, 3)),smallest_first=FALSE,rm1=FALSE)
nicify_cyclist(list(c(4, 6), c(7), c(2, 5, 1), c(8, 3)),smallest_first=FALSE,rm1=TRUE )
nicify_cyclist(list(c(4, 6), c(7), c(2, 5, 1), c(8, 3)),smallest_first=TRUE ,rm1=FALSE)
nicify_cyclist(list(c(4, 6), c(7), c(2, 5, 1), c(8, 3)),smallest_first=TRUE ,rm1=TRUE )

cyclist2word_single(list(c(1,4,3),c(7,8)))
```

---

derangement *Tests for a permutation being a derangement*

Description

A *derangement* is a permutation which leaves no element fixed.

Usage

```
is.derangement(x)
```

Arguments

x   Object to be tested

Value

A vector of Booleans corresponding to whether the permutations are derangements or not.

Note

The identity permutation is problematic because it potentially has zero size.

The identity element is not a derangement, although the (zero-size) identity cycle and permutation both return TRUE under the natural R idiom `all(P != seq_len(size(P)))`.

Examples

```
allperms(4)
is.derangement(allperms(4))

M <- matrix(c(1,2,3,4, 2,3,4,1, 3,2,4,1),byrow=TRUE,ncol=4)
M
is.derangement(word(M))

is.derangement(rperm(16,4))
```

---

dodecahedron   *The dodecahedron group*

Description

Permutations comprising the dodecahedron group on either its faces or its edges; also the full do-
decahedron group

Details

The package provides a number of objects for investigating dodecahedral groups:

Object dodecahedron_face is a cycle object with 60 elements corresponding to the permutations of
the faces of a dodecahedron, numbered 1-12 as in the megaminx net. Object dodecahedron_edge
is the corresponding object for permuting the edges of a dodecahedron. The edges are indexed by
the lower of the two adjoining facets on the megaminx net.

Objects full_dodecahedron_face and full_dodecahedron_edge give the 120 elements of the
full dodecahedron group, that is, the dodecahedron group including reflections. NB: these objects
are **not** isomorphic to S5.

Note

File zzz_dodecahedron.R is not really intended to be human-readable. The source file is in
inst/dodecahedron_group.py and inst/full_dodecahedron_group.py which contain docu-
mented python source code.

Examples

```
permprod(dodecahedron_face)
```

---

faro   *Faro shuffles*

Description

A *faro shuffle*, faro(),is a permutation of a deck of $2n$ cards. The cards are split into two packs,
1:n and (n+1):2n, and interleaved: cards are taken alternately from top of each pack and placed
face down on the table. A *faro out-shuffle* takes the first card from 1:n and a *faro in-shuffle* takes
the first card from (n+1):(2*n).

A *generalized faro shuffle*, faro_gen(), splits the pack into m equal parts and applies the same
permutation to each pack, and the same permutation to each set of packs, before interleaving.
The interleaving itself is simply a matrix transpose; it is possible to omit this step by passing
interleave=FALSE.

Usage

```
faro(n, out = TRUE)
faro_gen(n,m,p1=id,p2=id,interleave=TRUE)
```

Arguments

n	Number of cards in each pack
m	Number of packs
p1, p2	Permutations for cards and packs respectively, coerced to word form
interleave	Boolean, with default `TRUE` meaning to actually perform the interleaving and `FALSE` meaning not to
out	Boolean, with default `TRUE` meaning to return an out-shuffle and `FALSE` meaning to return an in-shuffle

Value

Returns a permutation in word form

Author(s)

Robin K. S. Hankin

Examples

```
faro(4)
faro(4,FALSE)

faro_gen(9,3)
faro_gen(7,4,cyc_len(7),cyc_len(4))
faro_gen(7,4,cyc_len(7),cyc_len(4),interleave=FALSE)

sapply(seq_len(10),function(n){permorder(faro(n,FALSE))}) # OEIS  A002326

plot(as.vector(as.word(faro(10))),type='b')
plot(as.vector(faro_gen(8,5,p1=cyc_len(8)^2,interleave=FALSE)))
```

---

fbin	*The fundamental bijection*

Description

Stanley defines the *fundamental bijection* on page 30.

Given $w = (14)(2)(375)(6)$, Stanley writes it in standard form (specifically: each cycle is written with its largest element first; cycles are written in increasing order of their largest element). Thus we obtain $(2)(41)(6)(753)$.

Then we obtain w^* from w by writing it in standard form an erasing the parentheses (that is, viewing the numbers as a *word*); here $w^* = 2416753$.

Given this, w may be recovered by inserting a left parenthesis preceding every left-to-right maximum, and right parentheses where appropriate.

Function `standard()` takes an object of class `cycle` and returns a list of cyclists. NB this does not return an object of class "cycle" because `cycle()` calls `nicify()`.

Function `standard_cyclist()` retains length-one cycles (compare `nicify_cyclist()`, which does not).

Usage

```
standard(cyc,n=NULL)
standard_cyclist(x,n=NULL)
fbin_single(vec)
fbin(W)
fbin_inv(cyc)
```

Arguments

vec	In function `fbin_single()`, an integer vector
W	In functions `fbin()` and `fbin_inv()`, an object of class permutation, coerced to word and cycle form respectively
cyc	In functions `fbin_single()` and `standard()`, permutation object coerced to cycle form
n	In function `standard()` and `standard_cyclist()`, size of the partition to assume, with default NULL meaning to use the largest element of any cycle
x	In function `standard_cyclist()`, a cyclist

Details

The user-friendly functions are `fbin()` and `fbin_inv()` which perform Stanley's "fundamental bijection". Function `fbin()` takes a word object and returns a cycle; function `fbin_inv()` takes a cycle and returns a word.

The other functions are low-level helper functions that are not really intended for the user (except possibly `standard()`, which puts a cycle object in standard order in list form).

nicify_cyclist

Examples

```
# Stanley's example w:
standard(cycle(list(list(c(1,4),c(3,7,5)))))

standard_cyclist(list(c(4, 6), c(7), c(2, 5, 1), c(8, 3)))

w_hat <- c(2,4,1,6,7,5,3)

fbin(w_hat)
fbin_inv(fbin(w_hat))

x <- rperm(40,9)
stopifnot(all(fbin(fbin_inv(x))==x))
stopifnot(all(fbin_inv(fbin(x))==x))
```

```
fixed                         Fixed elements
```

Description

Finds which elements of a permutation object are fixed

Usage

```
## S3 method for class 'word'
fixed(x)
## S3 method for class 'cycle'
fixed(x)
```

Arguments

x   Object of class `word` or `cycle`

Value

Returns a Boolean vector corresponding to the fixed elements of a permutation.

Note

The function is vectorized; if given a vector of permutations, `fixed()` returns a Boolean vector showing which elements are fixed by *all* of the permutations.

This function has two methods: `fixed.word()` and `fixed.cycle()`, neither of which coerce.

fixed(megaminx)
```

---

get1   *Retrieve particular cycles or components of cycles*

Description

Given an object of class cycle, function get1() returns a representative of each of the disjoint cycles in the object's elements. Function get_cyc() returns the cycle containing a specific element.

Usage

```
get1(x,drop=TRUE)
get_cyc(x,elt)
```

Arguments

x	permutation object (coerced to cycle class)
drop	In function get1(), argument drop controls the behaviour if x is length 1. If drop is TRUE, then a vector of representative elements is returned; if FALSE, then a list with one vector element is returned
elt	Length-one vector interpreted as a permutation object

Author(s)

Robin K. S. Hankin

Examples

```
data(megaminx)
get1(megaminx)
get1(megaminx[1])
get1(megaminx[1],drop=TRUE)

get_cyc(megaminx,11)
```

id   *The identity permutation*

Description

The *identity permutation* leaves every element fixed

Usage

```
is.id(x)
is.id_single_cycle(x)
## S3 method for class 'cycle'
is.id(x)
## S3 method for class 'list'
is.id(x)
## S3 method for class 'word'
is.id(x)
```

Arguments

x   Object to be tested

Details

The identity permutation is problematic because it potentially has zero size.

Value

The variable id is a *cycle* as this is more convenient than a zero-by-one matrix.

Function is.id() returns a Boolean with TRUE if the corresponding element is the identity, and FALSE otherwise. It dispatches to either is.id.cycle() or is.id.word() as appropriate.

Function is.id.list() tests a cyclist for identityness.

Note

The identity permutations documented here are distinct from the null permutations documented at nullperm.Rd.

is.id(id)

as.word(id)  # weird

x <- rperm(10,4)
x[3] <- id
is.id(x*inverse(x))
```

---

inverse   *Inverse of a permutation*

Description

Calculates the inverse of a permutation in either word or cycle form

Usage

```
inverse(x)
## S3 method for class 'word'
inverse(x)
## S3 method for class 'cycle'
inverse(x)
inverse_word_single(W)
inverse_cyclist_single(cyc)
```

Arguments

x	Object of class `permutation` to be inverted
W	In function `inverse_word_single()`, a vector corresponding to a permutation in word form (that is, one row of a `word` object)
cyc	In function `inverse_cyclist_single()`, a cyclist to be inverted

Details

The package provides methods to invert objects of class word (the R idiom is `W[W] <- seq_along(W)`) and also objects of class cycle (the idiom is `lapply(cyc,function(o){c(o[1],rev(o[-1]))})`).

The user should use `inverse()` directly, which dispatches to either `inverse.word()` or `inverse.cycle()` as appropriate.

Sometimes, using idiom such as `x^-1` or `id/x` gives neater code, although these may require coercion between word form and cycle form.

Value

Function `inverse()` returns an object of the same class as its argument.

Note

Inversion of words is ultimately performed by function `inverse_word_single()`:

```
inverse_word_single <- function(W){
    W[W] <- seq_along(W)
    return(W)
}
```

which can be replaced by `order()` although this is considerably less efficient, especially for small sizes of permutations. One of my longer-term plans is to implement this in C, although it is not clear that this will be any faster.

all(is.id(x*inverse(x)))  # should be TRUE

inverse(as.cycle(matrix(1:8,9,8)))
```

---

length   *Various vector-like utilities for permutation objects.*

Description

Various vector-like utilities for permutation objects such as `length`, `names()`, etc

Usage

```
## S3 method for class 'word'
length(x)
## S3 replacement method for class 'permutation'
length(x) <- value
## S3 method for class 'word'
names(x)
## S3 replacement method for class 'word'
names(x) <- value
```

Arguments

x	permutation object
value	In function names<-.word(), the new names

Details

These functions have methods only for word objects; cycle objects use the methods for lists. It is easy to confuse the *length* of a permutation with its size.

It is not possible to set the length of a permutation; this is more trouble than it is worth.

[size](#)

Examples

```
x <- rperm(5,9)
x
names(x) <- letters[1:5]
x

megaminx
length(megaminx)   # the megaminx group has 12 generators, one per face.
size(megaminx)     # the megaminx group is a subgroup of S_129.

names(megaminx) <- NULL   # prints more nicely.
megaminx
```

---

megaminx   *megaminx*

Description

A set of generators for the megaminx group

Details

Each element of megaminx corresponds to a clockwise turn of 72 degrees. See the vignette for more details.

megaminx[, 1]	W	White
megaminx[, 2]	Pu	Purple
megaminx[, 3]	DY	Dark Yellow

```
megaminx[, 4]   DB   Dark Blue
megaminx[, 5]   R    Red
megaminx[, 6]   DG   Dark Green
megaminx[, 7]   LG   Light Green
megaminx[, 8]   O    Orange
megaminx[, 9]   LB   Light Blue
megaminx[,10]   LY   Light Yellow
megaminx[,11]   Pi   Pink
megaminx[,12]   Gy   Gray
```

Vector megaminx_colours shows what colour each facet has at START. Object superflip is a megaminx operation that flips each of the 30 edges.

These objects can be generated by running script inst/megaminx.R, which includes some further discussion and technical documentation and creates file megaminx.rda which resides in the data/ directory.

megaminx_plotter   *Plotting routine for megaminx sequences*

Description

Plots a coloured diagram of a dodecahedron net representing a megaminx

Usage

```
megaminx_plotter(megperm=id,offset=c(0,0),M=diag(2),setup=TRUE,...)
```

Arguments

megperm	Permutation to be plotted
offset, M	Offset and transformation matrix, see details
setup	Boolean, with default TRUE meaning to set up the plot with a plot() statement, and FALSE meaning to plot the points on a pre-existing canvas
...	Further arguments passed to polygon()

Details

Function megaminx_plotter() plots a coloured diagram of a dodecahedron net representing a megaminx. The argument may be specified as a sequence of turns that are applied to the megaminx from *START*.

The function uses rather complicated internal variables pentagons, triangles, and quads whose meaning and genesis is discussed in heavily-documented file inst/guide.R.

The diagram is centered so that the common vertex of triangles 28 and 82 is at $(0, 0)$.

nullperm   *Null permutations*

Description

Null permutations are the equivalent of NULL

Usage

```
nullcycle
nullword
```

Format

Object `nullcycle` is an empty list coerced to class `cycle`, specifically `cycle(list())`

Object `nullword` is a zero-row matrix, coerced to `word`, specifically `word(matrix(integer(0),0,0))`

Details

These objects are here to deal with the case where a length-zero permutation is extracted. The behaviour of these null objects is not entirely consistent.

Note

The objects documented here are distinct from the identity permutation, `id`, documented separately.

See Also

[id](id)

Examples

```

as.cycle(1:5)[0]  # null cycle

data(megaminx)
c(NULL,megaminx)       # probably not what the user intended...
c(nullcycle,megaminx) # more useful.
c(id,megaminx)         # also useful.
```

Ops.permutation   *Arithmetic Ops Group Methods for permutations*

Description

Allows arithmetic operators to be used for manipulation of permutation objects such as addition, multiplication, division, integer powers, etc.

Usage

```
## S3 method for class 'permutation'
Ops(e1, e2)
cycle_power(x,pow)
cycle_power_single(x,pow)
cycle_sum(e1,e2)
cycle_sum_single(c1,c2)
word_equal(e1,e2)
word_prod(e1,e2)
word_prod_single(e1,e2)
permprod(x)
vps(vec,pow)
ccps(n,pow)
helper(e1,e2)
cycle_plus_integer_elementwise(x,y)
conjugation(e1,e2)
```

Arguments

x, e1, e2	Objects of class "permutation"
c1, c2	Objects of class cycle
pow	Integer vector of powers
vec	In function vps(), a vector of integers corresponding to a cycle
n	In function ccps(), the integer power to which cycle(seq_len(n)) is to be raised; may be positive or negative
y	In experimental function cycle_plus_integer_elementwise(), an integer

Details

Function Ops.permutation() passes binary arithmetic operators ("+", "*", "/", "^", and "==") to the appropriate specialist function.

Multiplication, as in a*b, is effectively word_prod(a,b); it coerces its arguments to word form (because a*b = b[a]).

Raising permutations to integer powers, as in a^n, is cycle_power(a,n); it coerces a to cycle form and returns a cycle (even if $n = 1$). Negative and zero values of n operate as expected. Function cycle_power() is vectorized; it calls cycle_power_single(), which is not. This calls vps() ("Vector Power Single"), which checks for simple cases such as pow=0 or the identity permutation; and function vps() calls function ccps() which performs the actual number-theoretic manipulation to raise a cycle to a power.

Group-theoretic conjugation is implemented: in package idiom, a^b gives inverse(b)*a*b. The notation is motivated by the identities x^(yz)=(x^y)^z and (xy)^z=x^z*y^z [or $x^{yz} = (x^y)^z$ and $(xy)^z = x^z y^z$]. Internally, conjugation() is called. The concept of conjugate *permutations* [that is, permutations with the same shape()] is discussed at conjugate.

The *sum* of two permutations a and b, as in a+b, is defined if the cycle representations of the addends are disjoint. The sum is defined as the permutation given by juxtaposing the cycles of a with those of b. Note that this operation is commutative. If a and b do not have disjoint cycle representations, an error is returned. This is useful if you want to guarantee that two permutations commute (NB: permutation a commutes with a^i for i any integer, and in particular a commutes with itself. But a+a returns an error: the operation checks for disjointness, not commutativity).

Permutation "division", as in a/b, is a*inverse(b). Note that a/b*c is evaluated left to right so is equivalent to a*inverse(b)*c. See note.

Function helper() sorts out recycling for binary functions, the behaviour of which is inherited from cbind(), which also handles the names of the returned permutation.

Experimental functionality is provided to define the "sum" of a permutation and an integer. If x is a permutation in cycle form with $x = (abc)$, say, and n an integer, then $x + n = (a + n, b + n, c + n)$: each element of each cycle of x is increased by n. Note that this has associativity consequences. For example, x+(x+n) might be defined but not (x+x)+n, as the two "+" operators have different interpretations. Distributivity is similarly broken (see the examples). Package idiom includes x-n [defined as x + (-n)] and n+x but not n-x as inverses are defined multiplicatively. The implementation is vectorised.

Value

None of these functions are really intended for the end user: use the ops as shown in the examples section.

Note

The class of the returned object is the appropriate one.

Unary operators to invert a permutation are problematic in the package. I do not like using "id/x" to represent a permutation inverse: the idiom introduces an utterly redundant object ("id"), and forces the use of a binary operator where a unary operator is needed. Similar comments apply to "x^-1", which again introduces a redundant object (-1) and uses a binary operator.

Currently, "-x" returns the multiplicative inverse of x, but this is not entirely satisfactory either, as it uses additive notation: the rest of the package uses multiplicative notation. Thus x*-x == id, which looks a little odd but OTOH noone has a problem with x^-1 for inverses.

I would like to follow APL and use "/x", but this does not seem to be possible in R. The natural unary operator would be the exclamation mark "!x". However, redefining the exclamation mark to give permutation inverses, while possible, is not desirable because its precedence is too low. One would like !x*y to return inverse(x)*y but instead standard precedence rules means that it returns inverse(x*y). Earlier versions of the package interpreted !x as inverse(x), but it was a disaster: to implement the commutator $[x, y] = x^{-1}y^{-1}xy$, for example, one would like to use !x*!y*x*y, but this is interpreted as !(x*(!y*(x*y))); one has to use (!x)*(!y)*x*y. I found myself having to use heaps of brackets everywhere. This caused such severe cognitive dissonance that I removed exclamation mark for inverses from the package. I might reinstate it in the future. There does not appear to be a way to define a new unary operator due to the construction of the parser.

Author(s)

Robin K. S. Hankin

Examples

```
x <- rperm(10,9) # word form
y <- rperm(10,9) # word form

x*y  # products are given in word form but the print method coerces to cycle form
print_word(x*y)

x^5  # powers are given in cycle form

x^as.cycle(1:5)  # conjugation (not integer power!); coerced to word.

x*inverse(x) == id  # all TRUE

# the 'sum' of two permutations is defined if their cycles are disjoint:
as.cycle(1:4) + as.cycle(7:9)

data(megaminx)
```

```
megaminx[1] + megaminx[7:12]

rperm() + 100

z <- cyc_len(4)
z
z+100
z + 0:5
(z + 0:5)*z

w <- cyc_len(7) + 1
(w+1)*(w-1)
```

---

orbit   *Orbits of integers*

Description

Finds the orbit of a given integer

Usage

```
orbit_single(c1,n1)
orbit(cyc,n)
```

Arguments

c1, n1	In (low-level) function `orbit_single()`, a cyclist and an integer vector respectively
cyc, n	In (vectorized) function `orbit()`, `cyc` is coerced to a cycle, and `n` is an integer vector

Value

Given a cyclist `c1` and integer `n1`, function `orbit_single()` returns the single cycle containing integer `n1`. This is a low-level function, not intended for the end-user.

Function `orbit()` is the vectorized equivalent of `orbit_single()`. Vectorization is inherited from `cbind()`.

The orbit of a fixed point p is $\{p\}$; the code uses an ugly hack to ensure that this is the case.

Note

Orbits are useful in a more general group theoretic context. Consider a finite group G acting on a set X, that is

$$\alpha\colon G \times X \longrightarrow X.$$

Writing $\alpha(g,x) = gx$, we define α to be a *group action* if $ex = x$ and $g(hx) = (gh)x$ where $g, h \in G$ and e is the group identity. For any $x \in X$ we define the *orbit Gx* of x to be the set of elements of X to which x can be moved by an element of G. Symbolically:

$$Gx = \{gx \colon g \in G\}$$

Now, we abuse notation slightly. In the context of permutation groups, we consider a fixed permutation σ. We consider the group $G = \langle \sigma \rangle$, that is, the group *generated by* σ; the group action is that of G on set $X = \{1, 2, \ldots, n\}$ with the obvious definition $\sigma x = \sigma(x)$ for $\sigma \in G$ and $x \in X$. This clearly is a group action as $\mathrm{id}(x) = x$ and $\sigma(\mu x) = (\sigma\mu)x$.

$$Gx = \bigcup_{i \in \mathbb{Z}} \sigma^i(x)$$

Expressing σ in cycle form makes it easy to see that the orbit of any element x of X is just the other members in the cycle containing x. For example, consider $\sigma = (26)(348)$ and $x = 4$. Then

$$G = \langle (26)(348) \rangle = \bigcup_{i \in \mathbb{Z}} [(26)(348)]^i$$

Because we are only interested in the effects on $x = 4$, we only need to consider the cycle (348): this is the only cycle that affects $x = 4$, and the (26) cycle may be ignored as it does not affect element 4. So

$$G4 = \bigcup_{i \in \mathbb{Z}} (348)^i(4) = \{3, 4, 8\}$$

[observe the slight notational abuse above: "(348)" means "the function $f(\cdot)$ with $f(3) = 4$, $f(4) = 8$, and $f(8) = 3$"].

orbit(megaminx,13)
```

outer — *Outer product of vectors of permutations*

Description

The outer product of two vectors of permutations is the pairwise product of each element of the first with each element of the second.

Details

It works in much the same way as `base::outer()`. The third argument, `FUN`, as in `outer(X,Y,FUN="*")` is regular group-theoretic multiplication but can be replaced with + if you are sure that the cycles of `X` and `Y` are distinct, see the examples. Each element of the returned matrix is a one-element list.

The print method may have room for improvement.

Author(s)

Robin K. S. Hankin

Examples

```
(M <- outer(rperm(),rperm()))
outer(cyc_len(4) + 0:3, cyc_len(4) + 100:101,"+")  # OK because the cycles are distinct

do.call("c",M) # c(M) gives a list and unlist(a) gives a numeric vector
```

permorder — *The order of a permutation*

Description

Returns the order of a permutation P: the smallest strictly positive integer n for which P^n is the identity.

Usage

```
permorder(x, singly = TRUE)
```

Arguments

x	Permutation, coerced to `cycle` form
singly	Boolean, with default `TRUE` meaning to return the order of each element of the vector, and `FALSE` meaning to return the order of the vector itself (that is, the smallest strictly positive integer for which `all(x^n==id)`).

Details

Coerces its argument to cycle form.

The order of the identity permutation is 1.

Note

Uses `mLCM()` from the `numbers` package.

```

| permutation | *Functions to create and coerce word objects and cycle objects* |

Description

Functions to create permutation objects. `permutation` is a virtual class.

Usage

```
word(M)
permutation(x)
is.permutation(x)
cycle(x)
is.word(x)
is.cycle(x)
as.word(x,n=NULL)
as.cycle(x)
cycle2word(x,n=NULL)
char2cycle(char)
cyc_len(n)
shift_cycle(n)
## S3 method for class 'word'
as.matrix(x,...)
```

Arguments

M	In function word(), a matrix with rows corresponding to permutations in word form
x	See details
n	In functions as.word() and cycle2word(), the size of the word to return; in function cyc_len(), the length of the cycles to return
char	In function char2cycle() a character vector which is coerced to a cycle object
...	Further arguments passed to as.matrix()

Details

Functions word() and cycle() are rather formal functions which make no attempt to coerce their arguments into sensible forms. The user should use permutation(), which detects the form of the input and dispatches to as.word() or as.cycle(), which are much more user-friendly and try quite hard to Do The Right Thing (tm).

Functions word() and cycle() are the only functions in the package which assign class word or cycle to an object.

Function word() takes a matrix and returns a word object; silently coerces to integer.

Function cycle() takes a "cyclist", that is, a list whose elements are lists whose elements are vectors (which are disjoint cycles); and returns an object of class "cycle". It nicifies its input with nicify_cyclist() before returning it.

A *word* is a matrix whose rows correspond to permutations in word format.

A *cycle* is a list whose elements correspond to permutations in cycle form. A cycle object comprises elements which are informally dubbed 'cyclists'. A cyclist is a list of integer vectors corresponding to the cycles of the permutation.

Function cycle2word() converts cycle objects to word objects.

Function shift_cycle() is a convenience wrapper for as.cycle(seq_len(n)); cyc_len() is a synonym.

It is a very common error (at least, it is for me) to use cycle() when you meant as.cycle().

The print method is sensitive to the value of option 'print_word_as_cycle', documented at print.Rd.

Function as.matrix.word() coerces a vector of permutations in word form to a matrix, each row of which is a word. To get a permutation matrix (that is, a square matrix of ones and zeros with exactly one entry of 1 in each row and each column), use perm_matrix().

In function as.word(), argument n cannot act to reduce the size of the word, only increase it. If you want to reduce the size, use trim() or tidy(). This function does not call word() except directly (e.g. it does not call size<-.word(), as this would give a recursion).

Value

Returns a cycle object or a word object

Author(s)

Robin K. S. Hankin

See Also

cyclist

Examples

```
word(matrix(1:8,7,8)) # default print method coerces to cycle form

cycle(list(list(c(1,8,2),c(3,6)),list(1:2, 4:8)))

char2cycle(c("(1,4)(6,7)","(3,4,2)(8,19)", "(56)","(12345)(78)","(78)"))

jj <- c(4,2,3,1)

as.word(jj)
as.cycle(jj)

as.cycle(1:2)*as.cycle(1:8) == as.cycle(1:8)*as.cycle(1:2)  # FALSE!

x <- rperm(10,7)
y <- rperm(10,7)
as.cycle(commutator(x,y))

cyc_len(1:9)
```

---

perm_matrix   *Permutation matrices*

Description

Given a permutation, coerce to word form and return the corresponding permutation matrix

Usage

```
perm_matrix(p,s=size(p))
is.perm_matrix(M)
pm_to_perm(M)
```

Arguments

p	Permutation, coerced to word form, of length 1
s	Size of permutation matrix or permutation
M	Permutation matrix

Details

Given a permutation p of size s, function `perm_matrix()` returns a square matrix with s rows and s columns. Entries are either 0 or 1; each row and each column has exactly one entry of 1 and the rest zero.

Row and column names of the permutation matrix are integers; this makes the printed version more compact.

Function `pm_to_perm()` takes a permutation matrix and returns the equivalent permutation in word form.

Note

Given a word p with size s, the idiom for `perm_matrix()` boils down to

```
M <- diag(s)
M[p,]
```

This is used explicitly in the `representations` vignette. There is another way:

```
M <- diag(s)
M[cbind(seq_len(s),p)] <- 1
M
```

which might be useful sometime.

See also the `representation` and `order_of_ops` vignettes, which discuss permutation matrices.

print   *Print methods for permutation objects*

Description

Print methods for permutation objects with matrix-like printing for words and bracket notation for cycle objects.

Usage

```
## S3 method for class 'cycle'
print(x, give_string=FALSE, ...)
## S3 method for class 'word'
print(x, h = getOption("print_word_as_cycle"), ...)
as.character_cyclist(y,comma=TRUE)
```

Arguments

x	Object of class permutation with word objects dispatched to print.word() and cycle objects dispatched to print.cycle()
h	Boolean, with default TRUE meaning to coerce words to cycle form before printing. See details
...	Further arguments (currently ignored)
y, comma	In as.character.cyclist(), argument y is a list of cycles (a cyclist); and comma is Boolean, specifying whether to include a comma in the output
give_string	In function

Details

Printing of word objects is controlled by options("print_word_as_cycle"). The default behaviour is to coerce a word to cycle form and print that, with a notice that the object itself was coerced from word.

If options("print_word_as_cycle") is FALSE, then objects of class word are printed as a matrix with rows being the permutations and fixed points indicated with a dot.

Function as.character_cyclist() is an internal function used by print.cycle(), and is not really designed for the end-user. It takes a cyclist and returns a character string.

Function `print_word()` and `print_cycle()` are provided for power users. These functions print their argument directly as word or cycle form; they coerce to the appropriate form. Use `print_word()` if you have a permutation in word form and want to inspect it as a word form but (for some reason) do not want to set `options("print_word_as_cycle")`. See `size.Rd` for a use-case.

Coercing a cycle to a character vector can be done with `as.character()`, which returns a character vector that is suitable for `as.cycle()`, so if a is a cycle `all(as.cycle(as.character(a)) == a)` will return `TRUE`. If you want to use the options of the print method, use `print.cycle(...,give_string=TRUE)`, which respects the print options discussed below. Neither of these give useful output if their argument is in word form.

The print method includes experimental functionality to display permutations of sets other than the default of integers $1, 2, \ldots, n$. Both cycle and word print methods are sensitive to option `perm_set`: the default value of `NULL` means to use integers. The symbols may be the elements of any character vector; use idiom such as

```
options("perm_set" = letters)
```

to override the default. But beware! If the permutation includes numbers greater than the length of `perm_set`, then `NA` will be printed. It is possible to use vectors with elements of more than one character (e.g. `state.abb`).

In the printing of cycle objects, commas are controlled with option `"comma"`. The default `NULL` means including commas in the representation if the size of the permutation exceeds 9. This works well for integers but is less suitable when using letters or state abbreviations. Force the use of commas by setting the option to `TRUE` or `FALSE`, e.g.

```
options("comma" = TRUE)
```

The print method does not change the internal representation of word or cycle objects, it only affects how they are printed.

The print method is sensitive to experimental option `print_in_length_order` (via function `as.character_cyclist()`). If `TRUE`, permutations cycle form will be printed but with the cycles in increasing length order. Set it with

```
options("print_in_length_order" = TRUE)
```

There is a package vignette (type `vignette("print")` at the command line) which gives more details and long-form documentation.

Value

Returns its argument invisibly, after printing it (except for `print.cycle(x,give_string=TRUE)`, in which case a character vector is returned).

nicify_cyclist

Examples

```
# generate a permutation in *word* form:
x <- rperm(4,9)

# default behaviour is to print in cycle form irregardless:
x

# change default using options():
options(print_word_as_cycle=FALSE)

# objects in word form now printed using matrix notation:
x

# printing of cycle form objects not altered:
as.cycle(x)

# restore default:
options(print_word_as_cycle=TRUE)

as.character_cyclist(list(1:4,10:11,20:33))  # x a cyclist;
as.character_cyclist(list(c(1,5,4),c(2,2)))  # does not check for consistency
as.character_cyclist(list(c(1,5,4),c(2,9)),comma=FALSE)

options("perm_set" = letters)
rperm(r=9)
options("perm_set" = NULL)  # restore default
```

---

rperm   *Random permutations*

Description

Function rperm() creates a word object of random permutations. Function rcyc() creates random permutations comprising a single (group-theoretic) cycle of a specified length. Functions r1cyc() and rgs1() are low-level helper functions.

Usage

```
rperm(n=10,r=7,moved=NA)
rcyc(n,len,r=len)
r1cyc(len,vec)
rgs1(s)
rgivenshape(n,s,size=sum(s))
```

Arguments

n	Number of permutations to create
r	Size of permutations
len	Length of cycles in `rcyc()` and `r1cyc()`
moved	In function `rperm()`, integer specifying how many elements can move (that is, how many elements do not map to themselves), with default `NA` meaning to choose a permutation at random. This is useful if you want a permutation that has a compact cycle representation
vec	Vector of integers to generate a cycle from
s, size	Shape and size of permutations to create

Value

Returns an object of class `word`

Note

Argument `moved` specifies a *maximum* number of elements that do not map to themselves; the actual number of non-fixed elements might be lower (as some elements might map to themselves). You can control the number of non-fixed elements precisely with argument `len` of function `rcyc()`, although this will give only permutations with a single (group-theoretic) cycle.

Argument `s` of function `rgivensize()` can include 1s (ones). Although length-one cycles are dropped from the resulting permutation, it is sometimes useful to include them to increase the size of the result, see examples.

In function `rgivenshape()`, if primary argument `n` is a vector of length greater than 1, it is interpreted as the shape of the permutation, and a single random permutation is returned.

sgn   *Sign of a permutation*

Description

Returns the sign of a permutation

Usage

```
sgn(x)
is.even(x)
is.odd(x)
```

Arguments

x   permutation object

Details

The sign of a permutation is ± 1 depending on whether it is even or odd. A permutation is *even* if it can be written as a product of an even number of transpositions, and *odd* if it can be written as an odd number of transpositions. The map $\mathrm{sgn}\colon S_n \longrightarrow \{+1, -1\}$ is a homomorphism; see examples.

Note

Internally, function sgn() coerces to cycle form.

The sign of the null permutation is NULL.

shape

Examples

```
sgn(id)  # always problematic

sgn(rperm(10,5))

x <- rperm(40,6)
y <- rperm(40,6)
```

```
stopifnot(all(sgn(x*y) == sgn(x)*sgn(y)))   # sgn() is a homomorphism

z <- as.cycle(rperm(20,9,5))
z[is.even(z)]
z[is.odd(z)]
```

---

shape   *Shape of a permutation*

Description

Returns the shape of a permutation. If given a word, it coerces to cycle form.

Usage

```
shape(x, drop = TRUE,id1 = TRUE,decreasing = FALSE)
shape_cyclist(cyc,id1=TRUE)
padshape(x, drop = TRUE, n=NULL)
shapepart(x)
shapepart_cyclist(cyc,n=NULL)
```

Arguments

x	Object of class cycle (if not, coerced)
cyc	A cyclist
n	Integer governing the size of the partition assumed, with default NULL meaning to use the largest element
drop	Boolean, with default TRUE meaning to unlist if possible
id1	Boolean, with default TRUE in function shape_cyclist() meaning that the shape of the identity is "1" and FALSE meaning that the shape is NULL
decreasing	In function shape(), Boolean with default FALSE meaning to return the cycle lengths in the order given by nicify_cyclist() and TRUE meaning to sort in decreasing order

Value

Function shape() returns a list with elements representing the lengths of the component cycles.

Function shapepart() returns an object of class partition showing the permutation as a set partition of disjoint cycles.

Function padshape() returns a list of shapes but padded with ones so the total is the size of the permutation.

shapepart_cyclist() and shapepart_cyclist() are low-level helper functions.

Note

What I call "shape", others call the "cycle type", so you will sometimes see "cycle type determines conjugacy class" as a theorem.

shapepart_cyclist(list(1:4,8:9))
```

---

size   *Gets or sets the size of a permutation*

Description

The 'size' of a permutation is the cardinality of the set for which it is a bijection.

Usage

```
size(x)
addcols(M,n)
## S3 method for class 'word'
size(x)
## S3 method for class 'cycle'
size(x)
## S3 replacement method for class 'word'
size(x) <- value
## S3 replacement method for class 'cycle'
size(x) <- value
```

Arguments

x	A permutation object
M	A matrix that may be coerced to a word
n, value	the size to set to, an integer

Details

For a word object, the *size* is equal to the number of columns. For a cycle object, it is equal to the largest element of any cycle.

Function addcols() is a low-level function that operates on, and returns, a matrix. It just adds columns to the right of M, with values equal to their column numbers, thus corresponding to fixed elements. The resulting matrix has n columns. This function cannot remove columns, so if n<ncol(M) an error is returned.

Setting functions cannot decrease the size of a permutation; use trim() for this.

It is meaningless to change the size of a cycle object. Trying to do so will result in an error. But you can coerce cycle objects to word form, and change the size of that.

Function size<-.word() [as in size(x) <- 9] trims its argument down with trim() and then adds fixed elements if necessary. Compare addcols(), which works only on permutations in word form.

fixed

Examples

```
size(as.cycle(c("(17)","(123)(45)")))  # should be 7

x <- as.word(as.cycle("123"))
print_word(x)
size(x) <- 9
print_word(x)
```

```
size(as.cycle(1:5) + as.cycle(100:101))

size(id)
```

---

tidy   *Utilities to neaten permutation objects*

Description

Various utilities to neaten word objects by removing fixed elements

Usage

```
tidy(x)
trim(x)
```

Arguments

x   Object of class `word`, or in the case of `tidy()`, coerced to class `word`

Details

Function `trim()` takes a `word` and, starting from the right, strips off columns corresponding to fixed elements until it finds a non-fixed element. This makes no sense for `cycle` objects; if `x` is of class `cycle`, an error is returned.

Function `tidy()` is more aggressive. This firstly removes *all* fixed elements, then renames the non-fixed ones to match the new column numbers. The map is an isomorphism (sic) with respect to composition.

Value

Returns an object of class `word`

Note

Results in empty (that is, zero-column) words if a vector of identity permutations is given

Examples

```
as.cycle(5:3)+as.cycle(7:9)
tidy(as.cycle(5:3)+as.cycle(7:9))

as.cycle(tidy(c(as.cycle(1:2),as.cycle(6:7))))

nicify_cyclist(list(c(4,6), c(7), c(2,5,1), c(8,3)))

data(megaminx)
tidy(megaminx)  # has 120 columns, not 129
stopifnot(all(unique(sort(unlist(as.cycle(tidy(megaminx)),recursive=TRUE)))==1:120))

jj <- megaminx*megaminx[1]
stopifnot(identical(shape(jj),shape(tidy(jj))))  #tidy() does not change shape
```

---

valid   *Functions to validate permutations*

Description

Functions to validate permutation objects: if valid, return TRUE and if not valid, generate a warning() and return FALSE.

Function singleword.valid() takes an integer vector, interpreted as a word, and checks that it is a permutation of seq_len(max(x)).

Function cycle.valid() takes a cyclist and checks for disjoint cycles of strictly positive integers with no repeats.

Usage

```
singleword_valid(w)
cyclist_valid(x)
```

Arguments

x	In function cycle_valid(), a cyclist
w	In function singleword_valid(), an integer vector

Value

Returns either TRUE, or stops with an informative error message
